EPSR-test-ex82 dockato: no second rotation / one-sided second rotation

Program(s): dockato | chained passes: 1 | verification: ALL IDENTICAL (1 pass)

What this case tests

`dockato` [1] builds larger molecules from `.ato` building blocks: copies of the first molecule of a docking file are bonded onto free sites of a docked file, removing one atom of each to form the new bond. This case covers the branches without a dihedral reference atom on one or both molecules.

Code exercised

Fortran (original, fortran_src/):

- `dockato.f`: `dockato` (driver, parameters from command line or stdin), `rotatem`, `random_rotatem`, `search_unsaturated`, `find_valence`
- `dockato.f`: `test_overlap`, `bond_molecule` (ROT/DIH groups), `replace_references`, `add_neighbours`, `remove_atoms`, `clean_atom_types`
- `ato_manipulation_rev4.f`: `get_direct_bonds`, `get_rotgrp`, `centreofmass`, `ftype`; `ato_read_and_save.f`: `moloutc`

Rust (port, rust/epsr-core/src/):

- `tools/dockato.rs`: `run`, `rotatem`, `random_rotatem`, `search_unsaturated`, `find_valence`, `test_overlap`
- `tools/dockato.rs`: `bond_molecule`, `replace_references`, `add_neighbours`, `remove_atoms`, `clean_atom_types`, `get_direct_bonds`, `get_rotgrp`
- `ato.rs`: `State::moloutc` (ROT/DIH groups), `State::ftype`; `rng.rs`: `Ran1::ran1`

Physical system

The building block `WaterMolecule.ato` of EPSR-test: one water molecule (O1, H1, H1; O-H 0.976 Å, H-H 1.54 Å, SPC/E Lennard-Jones and charges [2]) in a 14.42 Å box at 300 K. Atom `atomd` of the new molecule is placed on `atomv`, the molecule is rotated so that its `atomdr` neighbour lies on the `atomvr` neighbour of `atomv` (equal bond lengths required), an optional second (dihedral) rotation about the new bond uses `atomdrr`/`atomvrr` (random angle in [dminrr, dmaxrr] from `ran1`, the Park-Miller generator with Bays-Durham shuffle [3,4], or a fixed dihedral that creates a DIH group when dminrr = dmaxrr), overlaps are tested with a distance factor, `atomd` and `atomvr` are removed and the new rotational group, bonds and atom types are updated. Water units are again joined by O-O bonds.

Inputs

Command line only. Run 1: atomdrr = atomvrr = `0`, angles 0 0, `nooverlaps` (factor 1.0), 3 molecules (`waternorot`); run 2: atomvrr = 0 only, angle range 10-170°, factor 1.0, 3 molecules (`waterhalf`).

How the accuracy was verified

`commands.txt` (2 program calls, run once) was run with the Fortran reference build (`rust/tools/build_fortran_reference.sh`: the original sources, gfortran -O2 -fno-tree-vectorize, single thread) and with the Rust `epsr-rs` on identical copies of the inputs, and every file written was compared byte for byte (`rust/tools/run_ex_test.sh`, `compare_outputs.py`; no masking except where noted below). The Fortran output is stored in `fortran_reference.tar.gz`. Result of the final regression run of the complete port: every file identical in 1 pass.

Each run writes one new `.ato` file (coordinates, bonds, rotational groups, atom types and the random-number state), compared byte for byte with the stored Fortran output. Run 1: no second rotation; since dminrr = dmaxrr DIH groups are still created (2 DIH groups in `waternorot.ato`). Run 2: the docking molecule is rotated by the random angle itself (2 ROT groups in `waterhalf.ato`). Both outputs hold 5 atoms (2 of the 3 requested dockings).

Notes

Fortran behaviour reproduced: the DIH groups of run 1 get the atom pair (0,0) because the Fortran reads `nbond(0)`, the preceding COMMON element, which is 0.
